Builder's Permit + RogueOS

Pre-execution authority for autonomous AI actions.

Stephen Zeitvogel | Founder & Chief Architect

RMG develops an architecture that separates what an agent can propose from what it is permitted to execute.

Capability is not authority.

An agent with access to business tools can affect files, customer communications and operational systems.

The business needs explicit boundaries: who authorized the action, what is allowed, and when that authority ends.

RMG focuses on the decision before an external action, with an accompanying decision record.

Propose. Permit. Record. Execute. Revoke.

Builder's Permit defines bounded authority before action: identity, scope, resources and limits.

The governed execution boundary evaluates the proposed operation against that authority.

Witness/evidence records the authorization decision and relevant execution context.

The architecture provides a revocation path. Enforcement coverage depends on the integration and implemented boundary.

A permission boundary, not a prompt promise.

The model proposes an action; it does not create its own authority.

RMG's RogueOS / RogueOST materials describe the control-plane and authority-enforcement architecture.

Shadow Rogue is the enforcement component/persona in the current technical framing. It acts within supplied authority; it does not invent authority.

The scope of any deployment must identify which tools and side effects pass through the governed boundary.

A common language for accountable action.

Identity: the principal requesting or performing an action. Consent: the authorizing mandate. Intent: the proposed operation.

Builder's Permit: bounded permission. Attestation: supporting assertions and checks.

Proof: verification artifacts. Witness: the recorded decision trace. Evolution: changes subject to governance.

These are architectural concepts. Their presence in a specification is distinct from demonstrated implementation.

Founder-authored work with a dated record.

Stephen Zeitvogel identifies the project's origin in his 2025 local-autonomy and governance work.

The supplied USPTO acknowledgment dated December 14, 2025 records named submissions under application 63/864,057, which lists an August 14, 2025 filing date.

Later materials expand the architecture and commercial presentation. Their preparation date is not automatically the origin date of the underlying work.

Receipt of a submission establishes that record; it does not establish patent grant, claim scope, or comparative industry priority.

Find the pain. Trace the cause. Fix the money.

Assessment: identify an operational bottleneck and the authority risks in a proposed automated workflow.

Implementation: define bounded actions, integrate the relevant execution boundary and record decisions.

Verification: compare outcomes against an agreed baseline and examine authorization failures and exceptions.

The proposed model combines scoped project work with ongoing architecture oversight. Contracted scope and pricing are agreed per engagement.

Make each deployment assessable.

Acceptance criteria can cover permitted actions, denied actions, expired or revoked authority, and decision-record completeness.

Those criteria are a validation framework, not a claim that this package includes completed independent conformance testing.

This presentation does not claim universal bit-for-bit replay, impossible bypass, deployed hardware enforcement, or automatic evidentiary admissibility.

Performance, security coverage and production readiness require evidence from the specific implementation.

FOUNDER

Stephen Zeitvogel

Founder & Chief Architect, Rogue Management Group, LLC. Charlotte, North Carolina.

His supplied biography and resume describe systems infrastructure, technical consulting, cybersecurity investigation, evidence preservation and business-to-engineering work.

His background also includes American Airlines ground operations, with time-sensitive procedures and operational accountability.

RMG's work connects authorization design with practical business workflows. No additional certifications are asserted in this presentation.

Bounded authority. Observable decisions.

RMG seeks conversations with organizations evaluating governed agent workflows and partners interested in the architecture.

The engagement starts with a defined use case, an authority boundary and measurable acceptance criteria.

Technical diligence can examine the specifications, available implementation artifacts and dated project records.
